Temperature, in degrees Fahrenheit, can be converted to degree Celsius by use of the following formula:

$$\text{degree Fahrenheit } (\text{°F}) \qquad \qquad \qquad \text{°C} = \frac{5}{9} (\text{°F} - 32) \qquad \qquad \qquad \text{degree Celsius } (\text{°C})$$

HYDROLOGIC AND WATER-QUALITY DATA FOR THE EAST RIVER BASIN IN NORTHEASTERN WISCONSIN

By Peter E. Hughes

ABSTRACT

Hydrologic and precipitation data and water-quality samples were collected by the U.S. Geological Survey from rivers in the East River basin in northeastern Wisconsin during 1985-86. The Fox Valley Water Quality Planning Agency suspected that agricultural and urban nonpoint-source discharges were contributing significantly to the degradation of water quality in the basin.

Two continuous record streamflow and water-quality gaging stations were established: one on the East River at Monroe Street in Green Bay and the other on Bower Creek at Sunnyview Road near De Pere. Streamflow for the 1986 water year was greater than twice the long-term (1967-86) average and precipitation was 33 percent greater than the long-term (1951-80) average. Average daily streamflow at the East River during the 1986 water year was 185 cubic feet per second. Average daily streamflow at Bower Creek was 6 cubic feet per second.

Suspended-sediment yields were greatest in Bower Creek—264 tons per square mile per year; yields were 125 tons per square mile per year at the East River site. Total-phosphorus yields at the Bower Creek gage were 2,680 pounds per square mile per year; yields were 1,130 pounds per square mile per year at the East River site. The measured yields of suspended sediment and total phosphorus from the East River site, during the 1986 water year, were significantly larger than the estimated average yields for the Fox River at Wrightstown. During a year of normal streamflow, the East River would probably contribute a maximum of 10 percent of the total suspended sediment and 9 percent of the total-phosphorus load transported to the mouth of the Fox River.

Dissolved-oxygen concentrations tended to decrease upstream from the mouth of the East River. The daily mean dissolved-oxygen concentration was often less than 5 milligrams per liter at all three of the East River monitoring locations. Minimum dissolved-oxygen concentrations of 1 to 2 milligrams per liter were recorded at all sites.

The acceptable fecal coliform level for recreational water quality of 200 counts per 100 milliliters was exceeded at the three East River sites and Bower Creek in more than half of the samples. More samples collected at the downstream sites on the East River at Monroe Street in Green Bay and at the Allouez Avenue bridge at Allouez contained fecal-coliform/fecal-streptococcus ratios that exceeded 4.0, indicating that the bacteria was of human origin rather than of animal.

Mean concentrations for 5-day biochemical oxygen demand, total-phosphorus concentration, fecal-coliform counts, and fecal-streptococcus counts were higher at Bower Creek than any of the other sites monitored during 1985-86. Mean chlorophyll *a* concentrations were highest at the East River sites at Monroe Street in Green Bay and at Allouez Avenue bridge at Allouez.

INTRODUCTION

Background

The Brown County Land Conservation Department has recognized that serious water-quality problems exist in the East River basin. Excessive sedimentation from erosion of the heavy clay soils, nutrient loadings from both agricultural and urban runoff, and low dissolved-oxygen concentrations are adversely affecting on the stream's ecology

(Fox Valley Water Quality Planning Agency, 1985). In 1982, the Fox Valley Water Quality Planning Agency (FVWQPA) nominated the East River basin for inclusion in the Wisconsin Fund Program, which provides funding for implementation of best-management practices to control water-pollution problems. In an effort to provide the necessary data to support this nomination of the East River as a Priority Watershed, the FVWQPA entered into a cooperative study with the U.S. Geological Survey. Contributors to this study include the Fox Valley Water Quality Planning Agency, Green Bay Metropolitan Sanitary District, Brown County Conservation Alliance, Kress Foundation, Brown County Planning Commission, Brown County Land Conservation Department, city of Green Bay, and the U.S. Geological Survey.

Purpose and Scope

The purpose of this report is to describe streamflow, precipitation, and water-quality conditions in the East River basin and the Bower Creek subbasin during the period March 1985 to October 1986. Specifically, the report describes (1) streamflow, (2) precipitation, (3) annual suspended-sediment and phosphorus loads, (4) water temperature and dissolved-oxygen concentrations, and (5) miscellaneous water-quality characteristics, including fecal-coliform and fecal-streptococcus count, 5-day biochemical oxygen demand (BOD-5), and chlorophyll a concentration.

Sampling stations to measure streamflow, precipitation, and water quality were installed in March 1985 at the East River at Monroe Street in Green Bay and at Bower Creek at Sunnyview Road near De Pere. Automatic water samplers were installed to collect samples during storm runoff for analyses of suspended-sediment and nutrient concentrations. Dissolved-oxygen meters and temperature probes were operated at four sites from June through October of 1985. The sampling sites (fig. 1) included East River at Monroe Street in Green Bay, Allouez Avenue bridge over the East River at Allouez, State Highway 32 near De Pere, and Bower Creek at Sunnyview Road near De Pere.

During the same period in 1986, only the East River gage at Monroe Street in Green Bay was instrumented to monitor dissolved-oxygen concen-

tration and temperature. During nonstorm periods, a local observer collected biweekly samples for sediment, nutrient, and chlorophyll a concentrations, and fecal-coliform and fecal-streptococcus counts at the three East River locations and at the Bower Creek gage. Precipitation records were obtained from the National Weather Service Station at Austin Straubel Field in Green Bay (fig. 1). A rain gage was located at the East River at Monroe Street streamflow-gaging station in Green Bay during nonfreezing periods.

Physical Setting

The East River flows parallel to the lower Fox River in Brown County, through the city of Green Bay, and joins the Fox River approximately 2 mi (miles) upstream from the mouth of the Fox River at Green Bay (fig. 1). The sources of water to the East River are primarily runoff direct from precipitation over the 145-mi² (square mile) basin and ground-water discharge to the river. The lower part of the basin from the mouth to approximately 8 mi upstream is part of the Green Bay estuary and is directly affected by the seiche activity in the bay.

Bower Creek is a major tributary to the East River, comprising 29 percent of the 41.6 mi² East River drainage. Bower Creek was chosen for study because the Brown County Land Conservation Department believed it has significant agricultural improvement potential based on present land-use practices. The monitoring location selected within the Bower Creek watershed was at Sunnyview Road; at that location, the drainage area is 4.89 mi².

Acknowledgments

The U.S. Geological Survey conducted the study in cooperation with the Fox Valley Water Quality Planning Agency (FVWQPA). Mr. William Elman, Executive Director of the FVWQPA, focused the concerns of other agencies and actively pursued the initiation of this study. Mr. David Wentland (FVWQPA) provided suggestions and guidance during the study. Other contributors to this study include the Green Bay Metropolitan Sanitary District, Brown County Planning Commission, Brown County Conservation Alliance, Brown

County Land Conservation Department, city of Green Bay, and the Kress Foundation.

HYDROLOGIC CONDITIONS DURING STUDY PERIOD

Hydrologic conditions in the basin were assessed to evaluate the water-quality data that were collected. Precipitation and streamflow are two important factors used to evaluate how the study period conditions related to long-term hydrologic conditions.

Precipitation

Total precipitation recorded at Green Bay was 38.36 in. (inches) during 1985 and 31.33 in. during 1986 (National Oceanic and Atmospheric Administration, 1985, 1986). The annual mean precipitation in 1985 and 1986 exceeded the 30-year (1951-80) mean annual precipitation by 37 and 12 percent, respectively. In 1985, August (8.03 in.) was the wettest month and June (2.21 in.) the driest. The wettest month in 1986 was September (7.51 in.) and the driest was May (1.15 in.). The maximum daily precipitation was 2.20 in. on September 10 for 1986, and was 2.23 in. on November 1 for 1985. Table 1 shows the monthly precipitation totals and the departures from normal for the 2 years of the study. The daily precipitation data for 1985-86, recorded at the Austin Straubel Field in Green Bay, is tabulated in Appendix A and depicted in figure 2.

5-year flood ²	--	--	--	4,400
10-year flood ²	--	--	--	5,500

¹ The annual 7-day minimum flow will be less than or equal to the n-year 7-day low flow on the average once every n-years.

² The annual instantaneous peak discharge will be greater than or equal to the n-year flood on the average once every n-years.

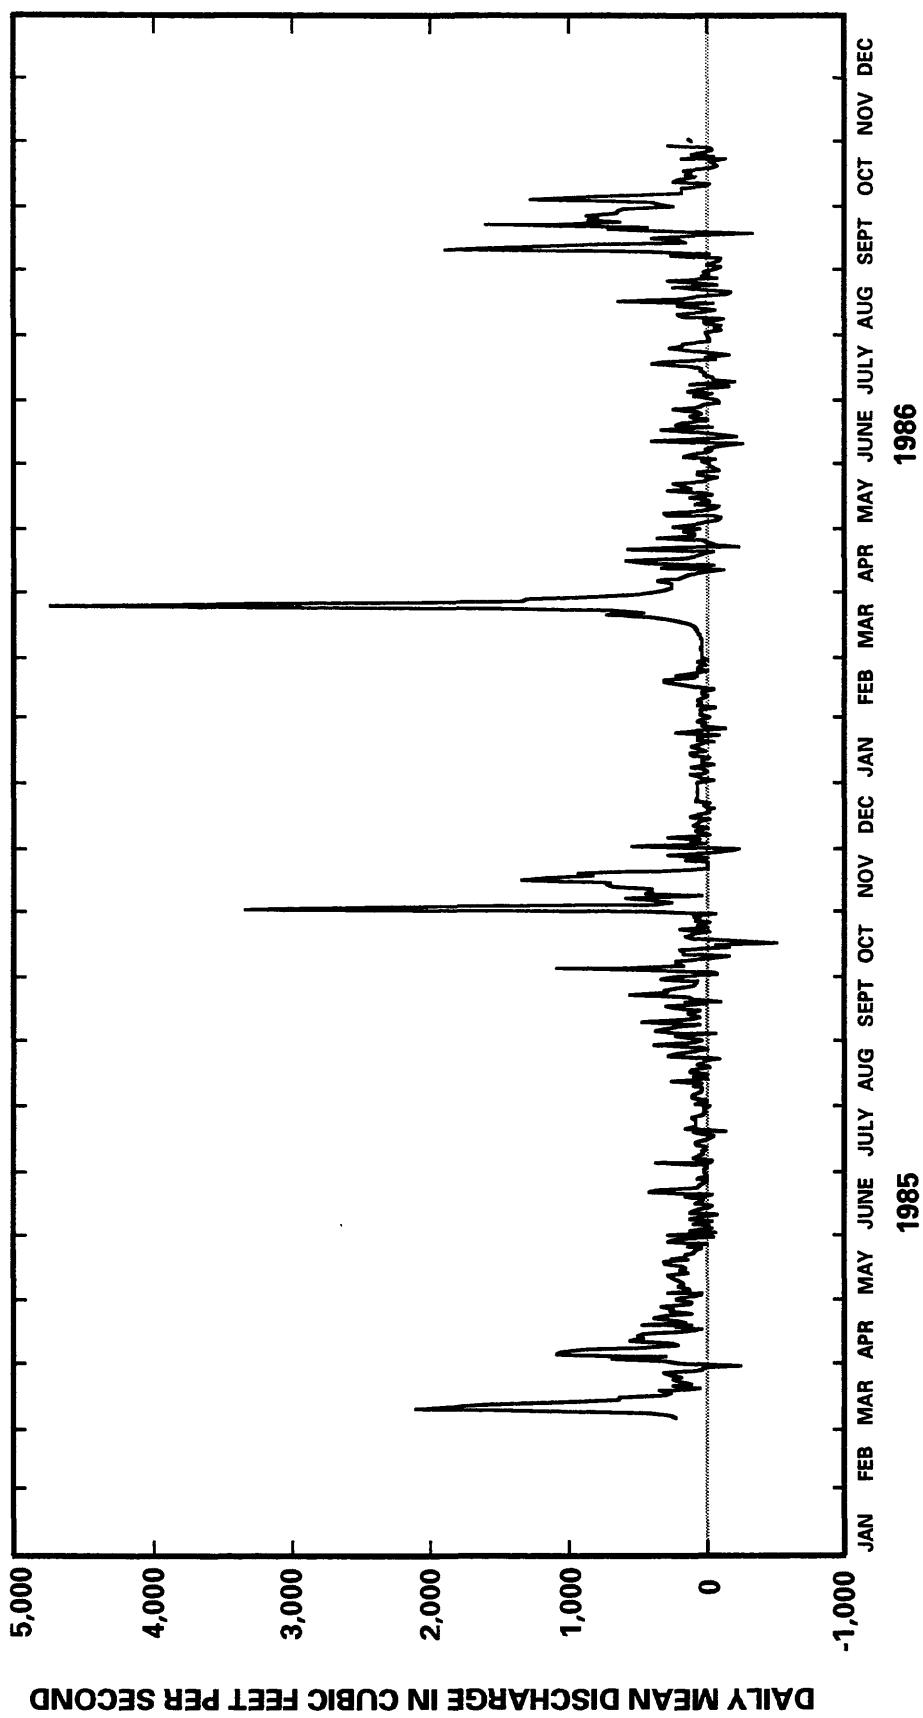

Figure 3. Daily mean discharge for East River at Monroe Street in Green Bay, 1985-1986.

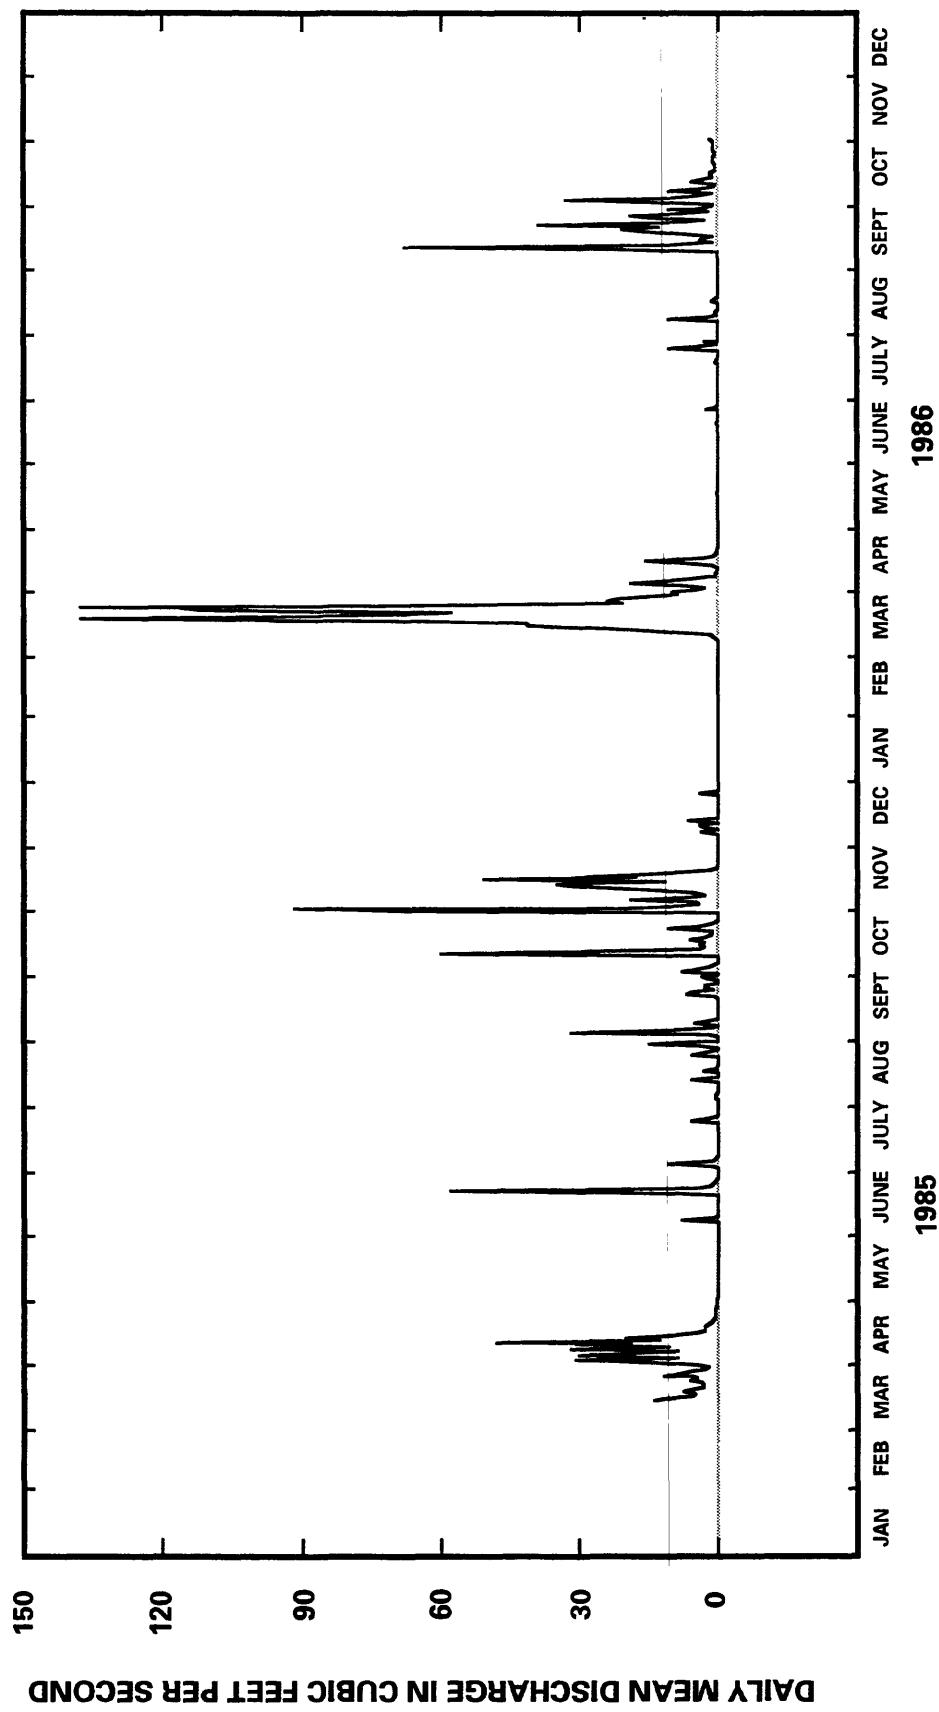

Figure 4. Daily mean discharge for Bower Creek at Sunnyview Road near De Pere, 1985-1986.

discharges for the Kewaunee River at Kewaunee (04085200) (Holmstrom and others, 1987), annual mean discharge for the 1986 water year was greater than twice the average for the 20-year period 1967-86. The maximum instantaneous discharge was slightly greater than a 10-year recurrence interval flood estimated by Conger (written commun., 1989).

The minimum 7-day low flow in 1986 was greater than the 2-year, 7-day low flow and was at about the 75 percent flow-duration level. In general, the annual minimum 7-day low flow will be less than or equal to the 2-year, 7-day low flow on average once every 2 years.

The use of an AVM for continuously measuring the velocity of the East River at Monroe Street in Green Bay was the only available method for determining the instantaneous discharge because of flow reversals. Accumulation of the water volume by a datalogger allowed flow proportional sampling for both downstream and upstream directions. A Westinghouse Model 801 Leading Edge Flow Meter¹ was used in this study. This instrument uses the time-of-travel method to determine the velocity between two points. One pair of 200 kilohertz transducers was securely mounted on opposite shores on a diagonal path 45 degrees to the centerline of the channel flow. A second pair of transducers was placed perpendicular to the first path. This crossed path was used to determine if an error in the angularity of the streamlines occurred during reverse flow in the channel (Laenen and Smith, 1983).

A major period of AVM interruption occurred during the March 1986 runoff. Submerged debris snagged the transducer cables and tore the cables from the transducers. Therefore, the discharge for the period from March 1 through April 10, 1986, was estimated from the daily discharge record of the Kewaunee River (04085200). The Kewaunee River was selected for comparison because it is close to the study area and has similar drainage-basin size (127 mi²).

WATER-QUALITY DATA

Chemical and Physical Characteristics

The chemical composition of suspended and dissolved solids and their discharge-weighted concentrations for samples taken in the East River and Bower Creek were measured as part of this study. A local observer collected daily water-quality samples from the East River at State Highway 32 near De Pere from May 1 through October 10, 1985. The samples were frozen until analysis. The samples were analyzed by the Robert E. Lee Labs in Green Bay for total phosphorus, BOD-5, and total suspended solids. Samples not used by Lee Labs were sent to the U.S. Geological Survey sediment lab in Iowa City, Iowa, for analysis of suspended sediment. Numerous samples were manually collected using the equal-width-increment method described by Guy and Norman (1970) to insure that the automatically collected samples represented average conditions in the stream cross section. Table 4 lists the ranges and means of constituent concentrations for each site for samples analyzed in 1985 and 1986. Data for the East River at Allouez Avenue bridge at Allouez and at State Highway 32 near De Pere are from the biweekly baseline sampling. Additional samples were collected daily from May 1 through October 1985 for the East River at State Highway 32 near De Pere. These samples were kept frozen until analysis by the University of Wisconsin-Green Bay. Data for the East River at Monroe Street in Green Bay and for Bower Creek at Sunnyview Road near De Pere include the baseline sample analyses and the event analyses. Bower Creek at Sunnyview Road near De Pere had the highest mean and high values for all constituents except chlorophyll a.

Total Phosphorus and Suspended Sediment

Chemical data and suspended-sediment concentrations for all sites are listed in Appendix C. Daily suspended-sediment and total-phosphorus

¹Analysis by UW Green Bay - samples frozen until analyzed.

loads for the East River at Monroe Street in Green Bay and State Highway 32 near De Pere and Bower Creek at Sunnyview Road near De Pere (given in Appendix D) were computed by streamflow and concentration integration techniques described by Porterfield (1972).

The largest suspended-sediment and total-phosphorus loads were observed for the East River at Monroe Street in Green Bay during the periods November 1-4, 1985, and March 25-28, 1986. As measured at the gaging station, 27 and 55 percent of the suspended sediment and 21 and 37 percent of the total phosphorus were transported within those periods for 1985 and 1986, respectively. At Bower Creek at Sunnyview Road near De Pere, 31 percent of the suspended-sediment load for 1985 was transported during one storm from June 21-25, and 19 percent of the total-phosphorus load for 1985 was transported during a second storm (November 1-4). In 1986,

one storm (March 16-26) had 63 percent of the suspended sediment and 38 percent of the total phosphorus transported.

Graphs were constructed to analyze the 1986 water year loading characteristics for the East River at Monroe Street in Green Bay and Bower Creek at Sunnyview Road near De Pere. By plotting the cumulative monthly sediment and phosphorus yield (figs. 5-6) versus time, seasonal changes in loadings become apparent and comparisons can be made between stations. The curves for suspended sediment show a steeper slope for the Bower Creek data and highlight the major contributing period during March 1986. The slopes for total-phosphorus loading are somewhat similar except for the extremely steep segment on Bower Creek during July 1986.

The particle-size distribution of the suspended sediments for the East River at Monroe Street in

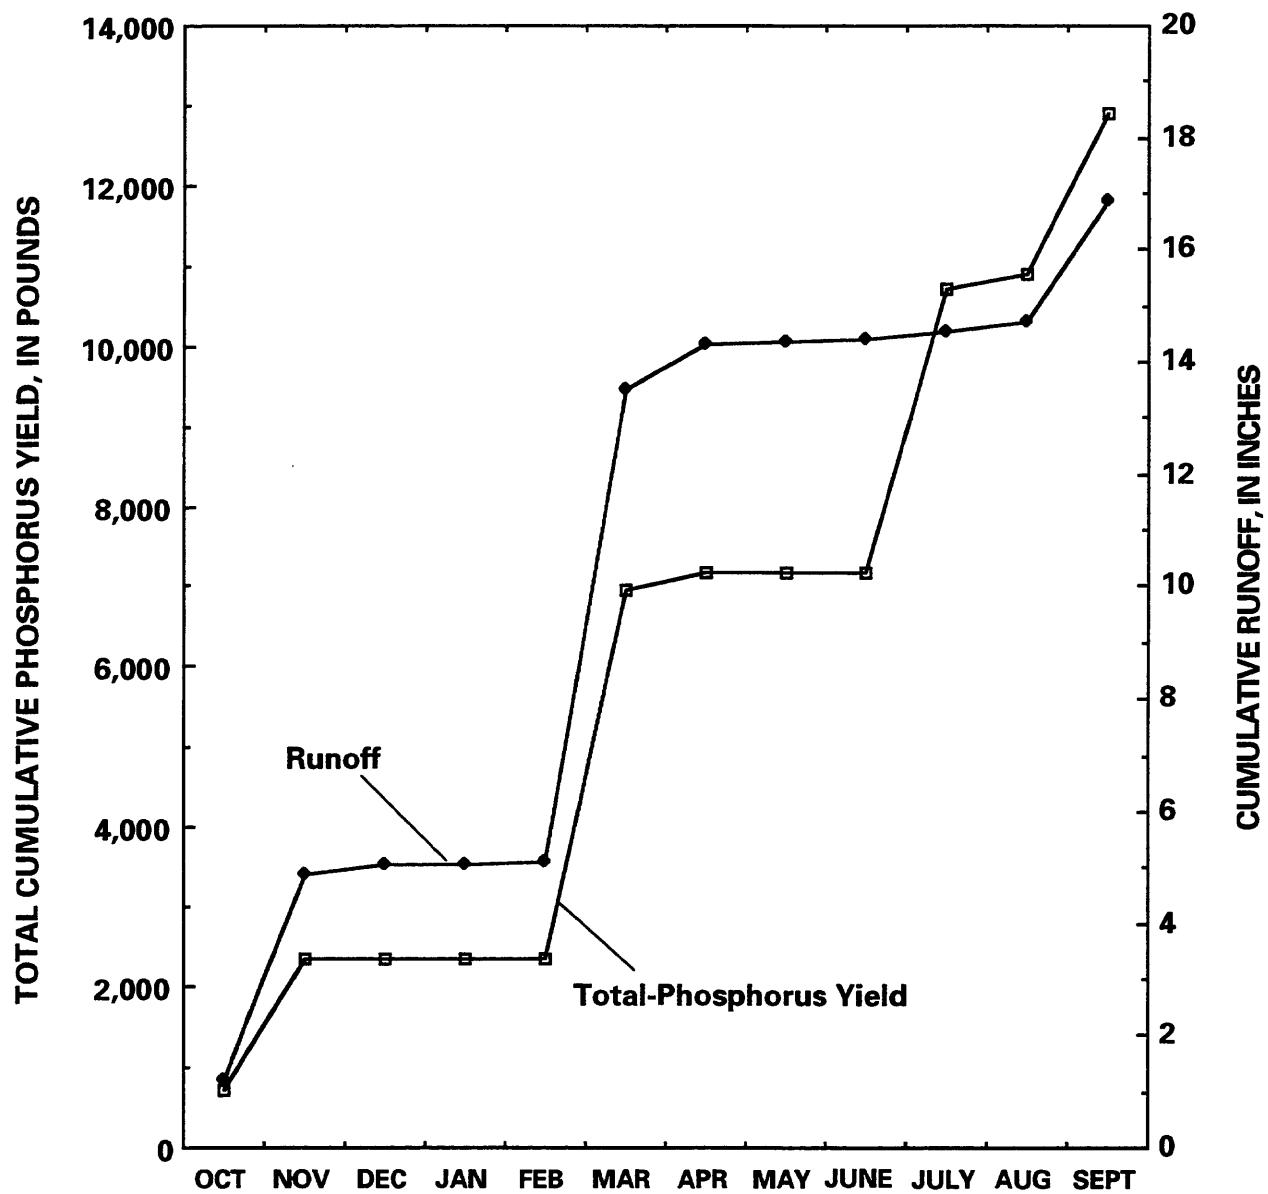

Figure 6b. Cumulative monthly runoff and total-phosphorus yield for Bower Creek at Sunnyview Road near De Pere, water year 1986.

Green Bay shows no appreciable difference between samples taken during downstream flow and samples taken during upstream flow. Table 5 summarizes the data for the large volume composite samples that were taken during 1985. For the periods monitored, more than 98 percent

of the suspended sediment was less than 0.062 mm (millimeters) in size. Approximately 65 percent of the suspended sediment was less than 0.004 mm (considered within the clay-sized range of particles).

Table 5.--Particle-size distribution of suspended sediment for East River at Monroe Street in Green Bay, 1985

[mm, millimeter; --, not determined]

Period	Flow direction	Suspended sediment					
		Percent finer than 0.062 mm	Percent finer than 0.031 mm	Percent finer than 0.016 mm	Percent finer than 0.008 mm	Percent finer than 0.004 mm	Percent finer than 0.002 mm

7/1 - 8/1/85	Downstream	97	--	88	83	67	53
7/1 - 8/1/85	Upstream	98	--	90	--	65	48

A summary of the sediment and phosphorus yields for the East River at Monroe Street in Green Bay and the Bower Creek at Sunnyview Road

near De Pere subbasin for the 1986 water year and the 1974-81 average yields for the Fox River at Wrightstown is shown below.

Site	Suspended-sediment yield [(ton/mi ²)/yr]	Total-phosphorus yield [(lb/mi ²)/yr]
East River at Monroe Street in Green Bay	125	1,130
Bower Creek at Sunnyview Road near De Pere	264	2,680
Fox River at Rapide Croche Dam near Wrightstown	16	172

Previous estimates of 14.6 (ton/mi²)/yr (tons per square mile per year) for sediment and 111 (lb/mi²)/yr (pounds per square mile per year) for phosphorus (Fox Valley Water Quality Planning Agency, 1985) are significantly less than the values determined during this study. The computed sediment load (125 (ton/mi²)/yr) from the East River for water year 1986 is eight times larger than the estimated 16 (ton/mi²)/yr average yields (1974-81) for the Lower Fox River near Wright-

town (Smith and others, 1982). The computed phosphorus load from the East River is seven times larger than the estimated average yield (1974-81) for the Fox River. Even though the discharge for the East River during 1986 was approximately twice that for an average year, the East River still contributes a disproportionately large share of the suspended-sediment and total-phosphorus yield to the Fox River basin when compared to the Fox River data available for the

Wrightstown gaging station. East River sediment and phosphorus yields for water year 1986 and yields measured at other Wisconsin gaging stations (Field and Duerk, 1988) are shown in figure 7 and listed in table 6. The data plotted in figure 7 show that the Fox River near Wrightstown has

the lowest sediment and phosphorus yields of the listed sites but also has the largest total drainage area ($6,050 \text{ mi}^2$). The East River shows a slightly higher yield of total phosphorus when compared to the other sites. The highest total-phosphorus yield of all the listed sites was for Bower Creek.

Table 6.--Suspended-sediment and total-phosphorus data for nonpoint-source gaging stations in Wisconsin

[mi^2 , square mile; --, no data available]

Station	Drainage area (mi^2)	Water year	Suspended sediment (tons per square mile)	Total phosphorus (pounds per square mile)
Steiner Branch	5.90	1978	369	707
		1979	85	231
Bruce Valley	10.10	1980	215	1,600
Elk Creek	99.70	1980	184	1,350
Onion River-Hingham	37.20	1979	79	331
		1980	64	317
Onion River-Sheboygan Falls	94.10	1979	88	528
		1980	76	517
Madden Branch	15.10	1981	239	749
		1982	684	2,290
Madden Branch tributary	2.83	1981	229	542
		1982	740	2,070
Pats Creek	5.40	1981	200	682
		1982	310	1,750
Apple River	9.30	1981	137	463
		1982	284	1,400
Yellowstone River	28.50	1978	220	--
		1979	54	--
White Creek	3.05	1982	983	710
Bower Creek	4.89	1986	264	2,680
East River	145.00	1986	125	1,130
Fox River-Wrightstown	6,050.00	1974-81	16	172

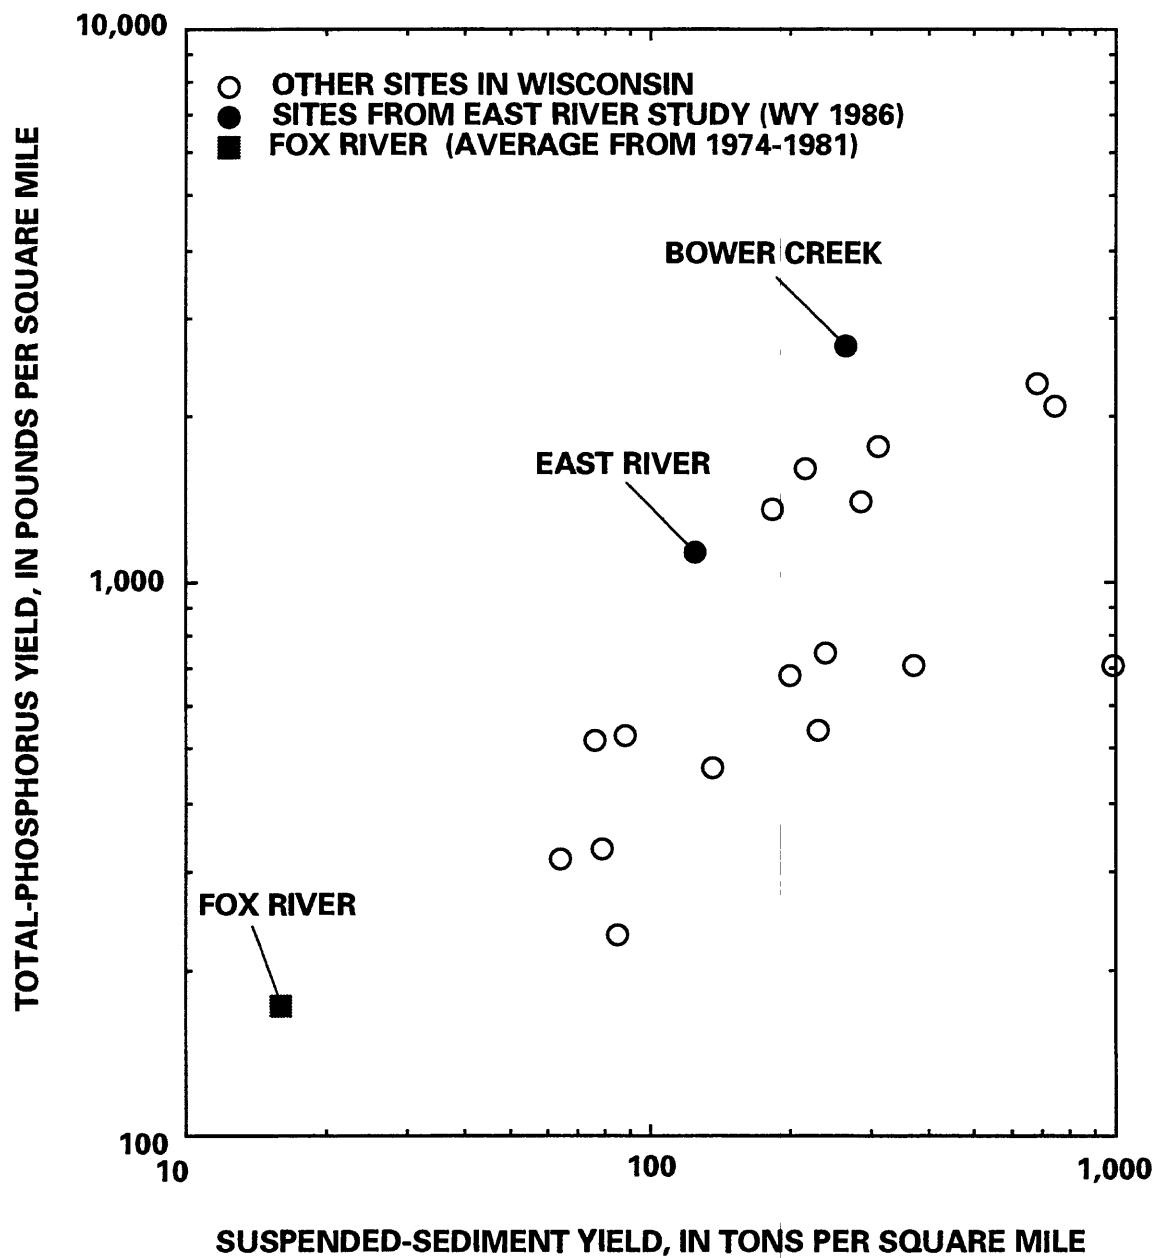

Figure 7. Relation of suspended-sediment and total-phosphorus yields for U.S. Geological Survey nonpoint-source gaging stations.

For the Bower Creek subbasin, the computed sediment yields are 2.1 times greater than those for the East River, and the phosphorus yields are 2.4 times greater. Smaller watersheds typically have higher yields on an areal unit basis (Field, 1985), and the relative areas of the two watersheds indicate that yields for the Bower Creek basin should be about twice as high as those for the East River.

Cropland erosion in the Bower Creek basin appears to be a more serious problem than in the East River basin. Soil Conservation Service (SCS) estimates indicate that 40 to 50 percent of the cropland in the Bower Creek basin has a high erosion potential (around 6 tons/acre)(Fox Valley Water Quality Planning Agency, 1985). Only 23 percent of the East River basin is estimated to have a similarly high erosion potential. Based on preliminary SCS observations (Fox Valley Water Quality Planning Agency, 1985), the Bower Creek basin appears to have problems with channel and stream-bank erosion.

Dissolved Oxygen and Water Temperature

Dissolved-oxygen concentrations and water temperature were monitored at three locations in the East River, at Bower Creek, and at one site on the Fox River during the 1985 field season. Reliable data were not obtained at the Allouez site until after August 1, 1985, because of equipment malfunctions. The daily mean dissolved-oxygen concentrations at the gage at Monroe Street in Green Bay were 2 to 3 mg/L (milligrams per liter) higher than at either the Allouez Avenue bridge or the State Highway 32 locations throughout the June through October 1985 period. The lowest daily mean concentrations of 1.7 mg/L occurred in June and July when water temperatures exceeded 25°C. Figure 8 shows the daily mean dissolved oxygen concentrations for the three East River sites for the period June-October 1985. The figure shows that dissolved-oxygen concentrations decrease with increasing distance upstream from the mouth. Appendix E lists daily maximum, minimum, and mean dissolved-oxygen concentrations for all the sites, including Bower Creek at Sunnyview Road near De Pere and the Fox River at the Schmidt Oil Dock. The daily maximum, minimum, and mean water temperatures for all the

sites monitored during 1985 are listed in Appendix F. The daily mean temperatures for the period of record and the mean daily dissolved oxygen for all the sites are shown in figures 8 to 14.

Dissolved oxygen and temperature were measured close to the top and bottom of the channel at the Schmidt Oil Dock near the mouth of the Fox River from August through October 1985. The daily mean dissolved oxygen for the upper site at the Schmidt Oil Dock and the East River at Monroe Street in Green Bay are shown in figure 15. It was expected that the ranges of concentrations would be similar between these sites because both locations are subject to reverse flow and are relatively close together. The daily mean dissolved-oxygen concentration for the East River prior to September was higher, and after September the Fox River concentration was higher.

Minimum instantaneous dissolved-oxygen concentrations in the East River at Monroe Street were commonly less than 5 mg/L throughout the study period; some concentrations were as low as 1 to 2 mg/L. Daily dissolved-oxygen concentrations fluctuated within as much as a 5 to 10 mg/L range between the minimum and maximum values. Dissolved-oxygen concentrations in Bower Creek at Sunnyview Road were also frequently less than 5 mg/L; the lowest concentrations were in the 1 to 2 mg/L range. The dissolved-oxygen sampling location on Bower Creek at Sunnyview Road was essentially a stagnant pool during periods of minimum discharge. Dissolved oxygen and temperature were measured at Bower Creek from June through October of 1985.

The only gaging station operated for dissolved-oxygen and temperature monitoring during 1986 was the East River at Monroe Street in Green Bay. The data for June-October 1986 is listed in Appendix E and F.

Bacteria

Fecal coliform and fecal streptococcus were monitored biweekly at the three East River locations and the Bower Creek at Sunnyview Road near De Pere location. The East River at Monroe Street in Green Bay and the Bower Creek sites also were sampled during some storm events.

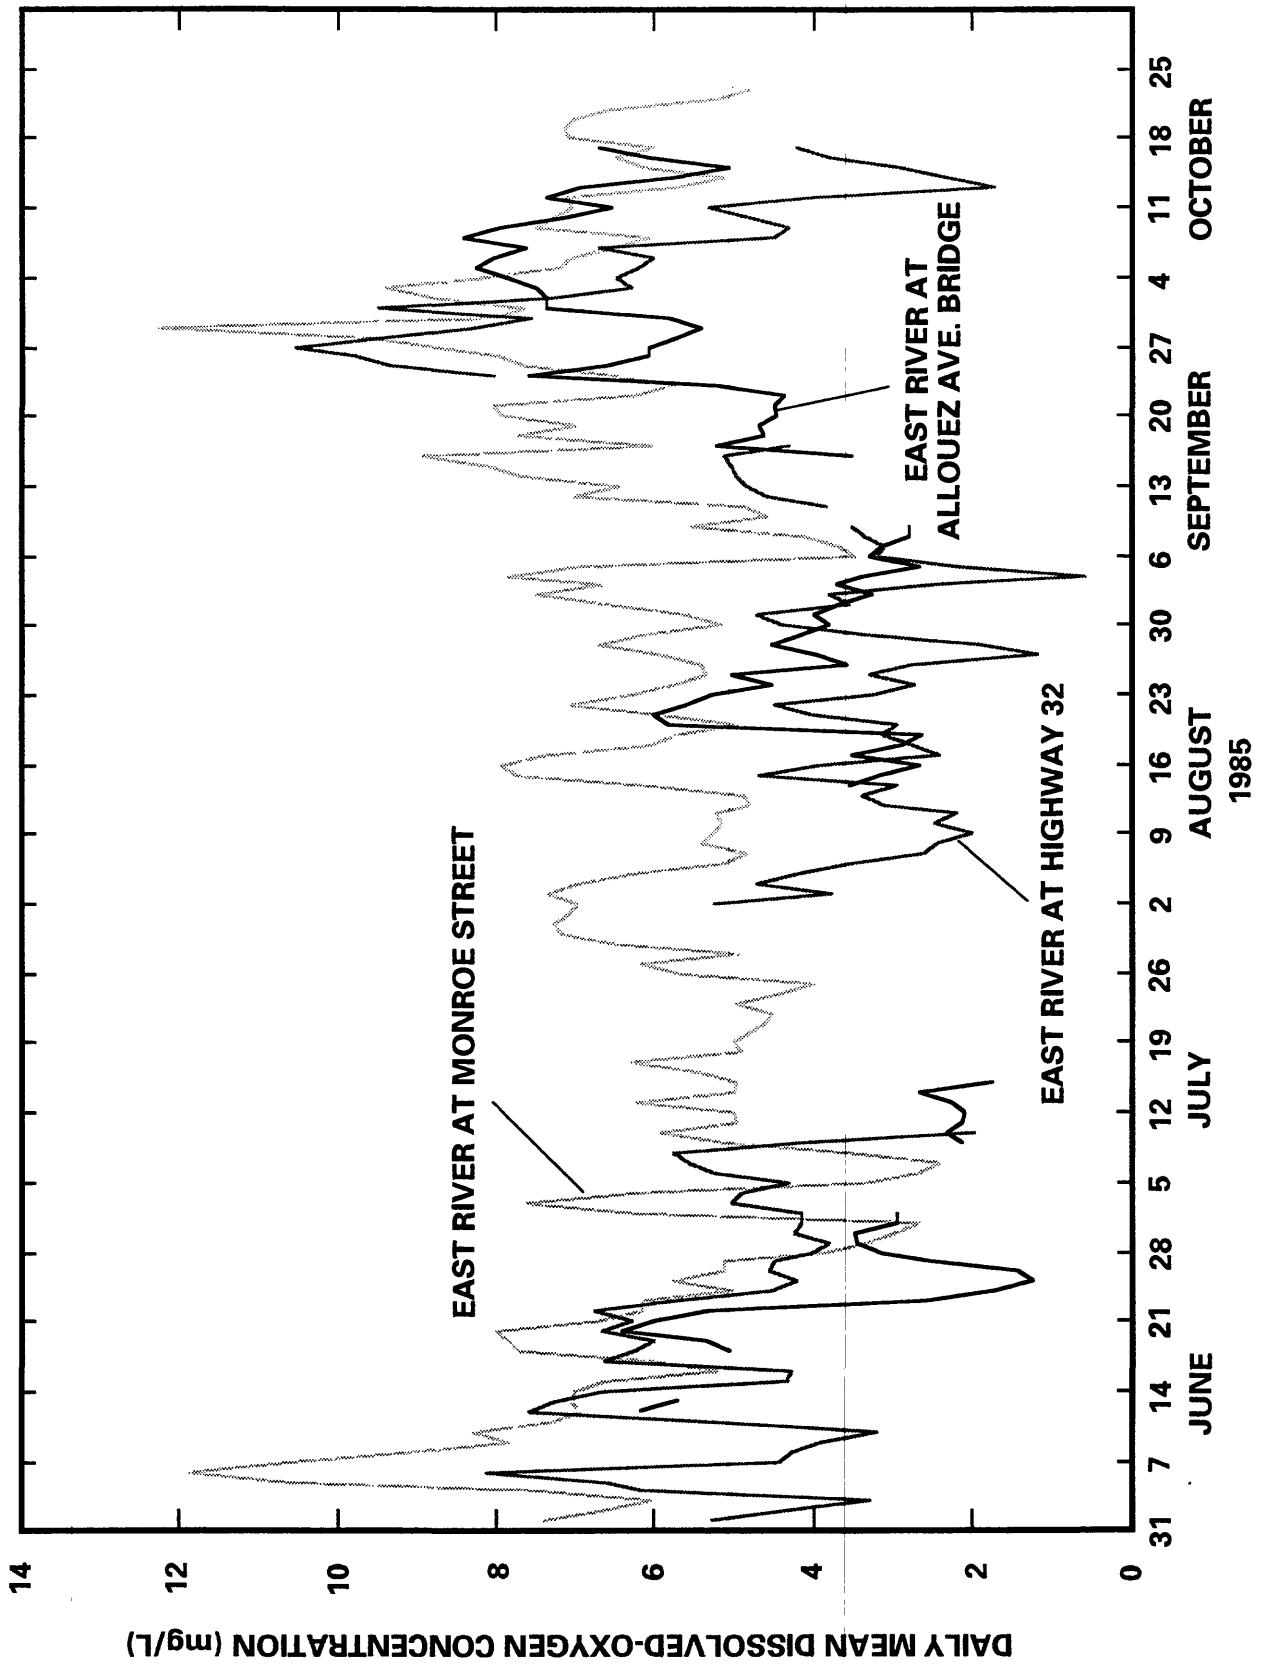

Figure 8. Daily mean dissolved-oxygen concentration for East River at Monroe Street in Green Bay, at Allouez Avenue bridge at Allouez, and at State Highway 32 near De Pere, June-October 1985.

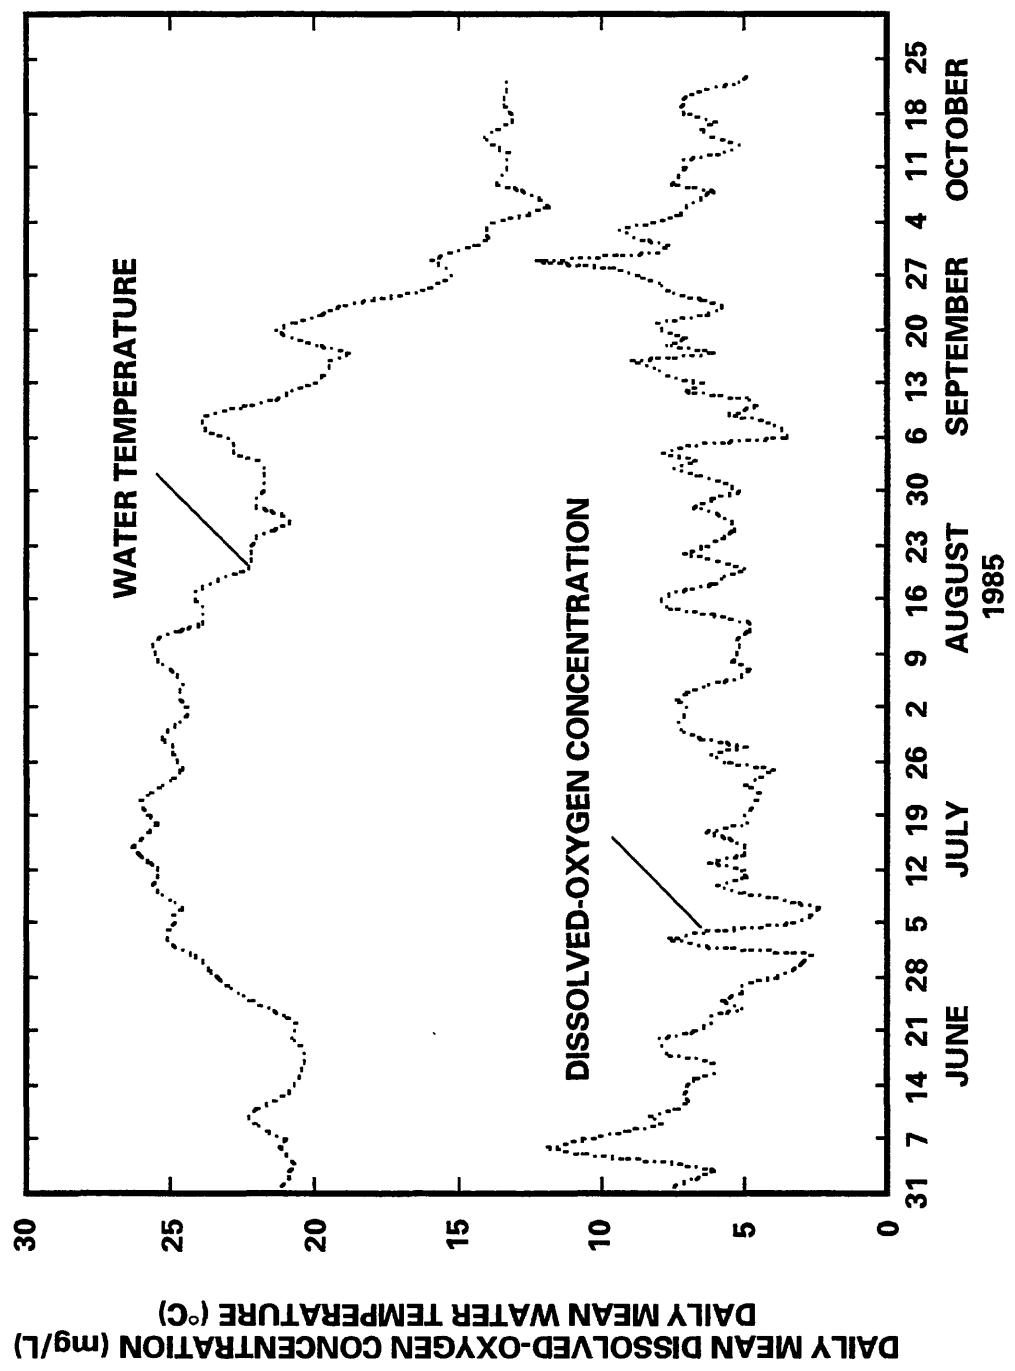

Figure 9. Daily mean dissolved-oxygen concentration and daily mean water temperature for East River at Monroe Street in Green Bay, June–October 1985.

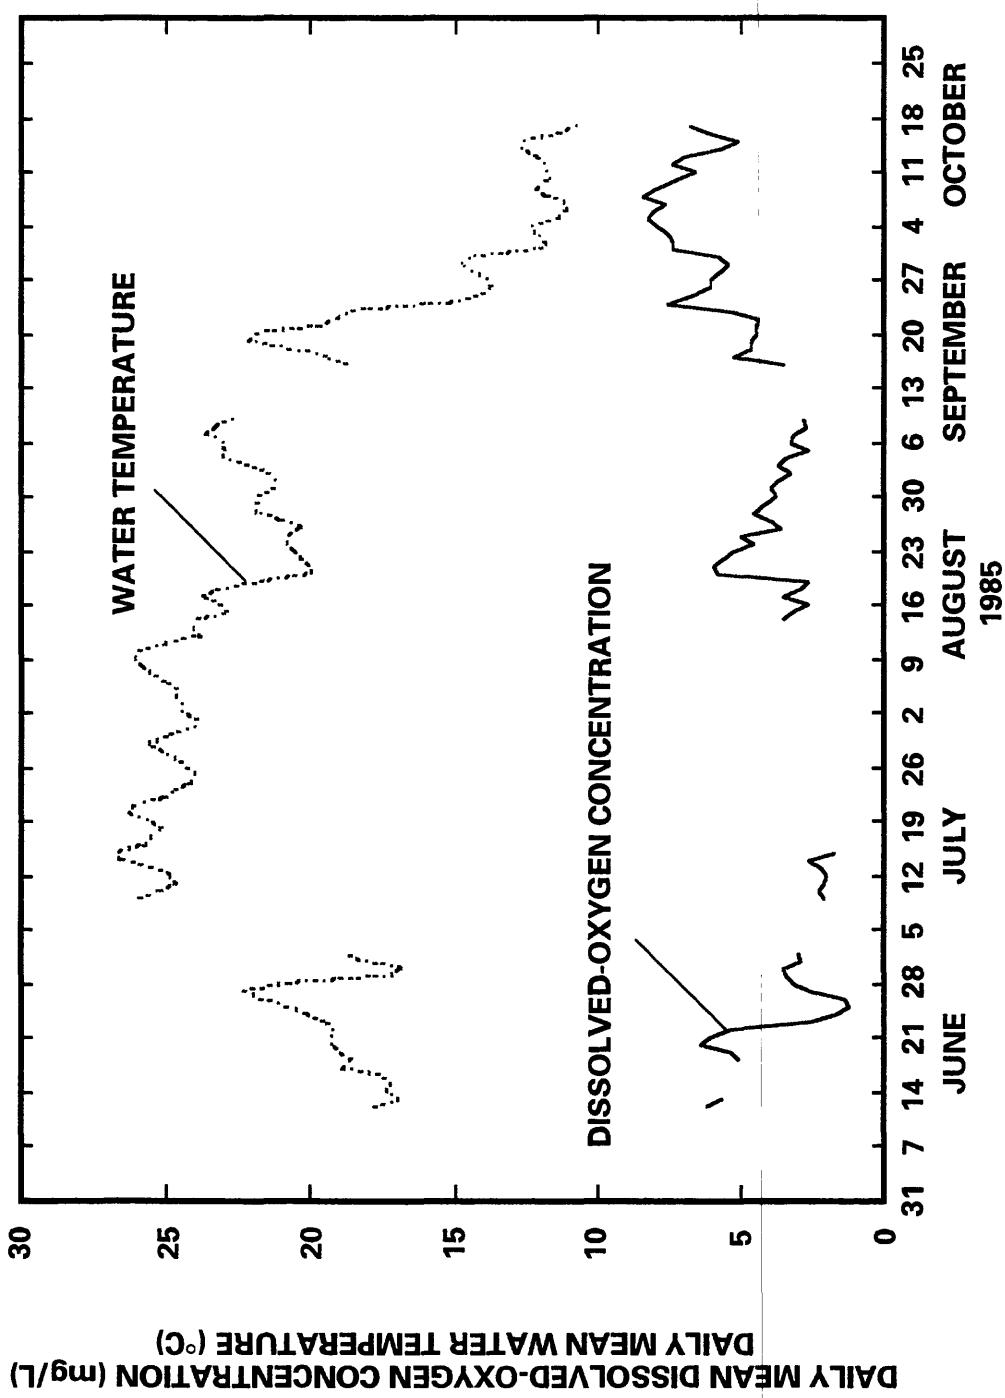

Figure 10. Daily mean dissolved-oxygen concentration and daily mean water temperature for East River at Allouez Avenue bridge at Allouez, June-October 1985.

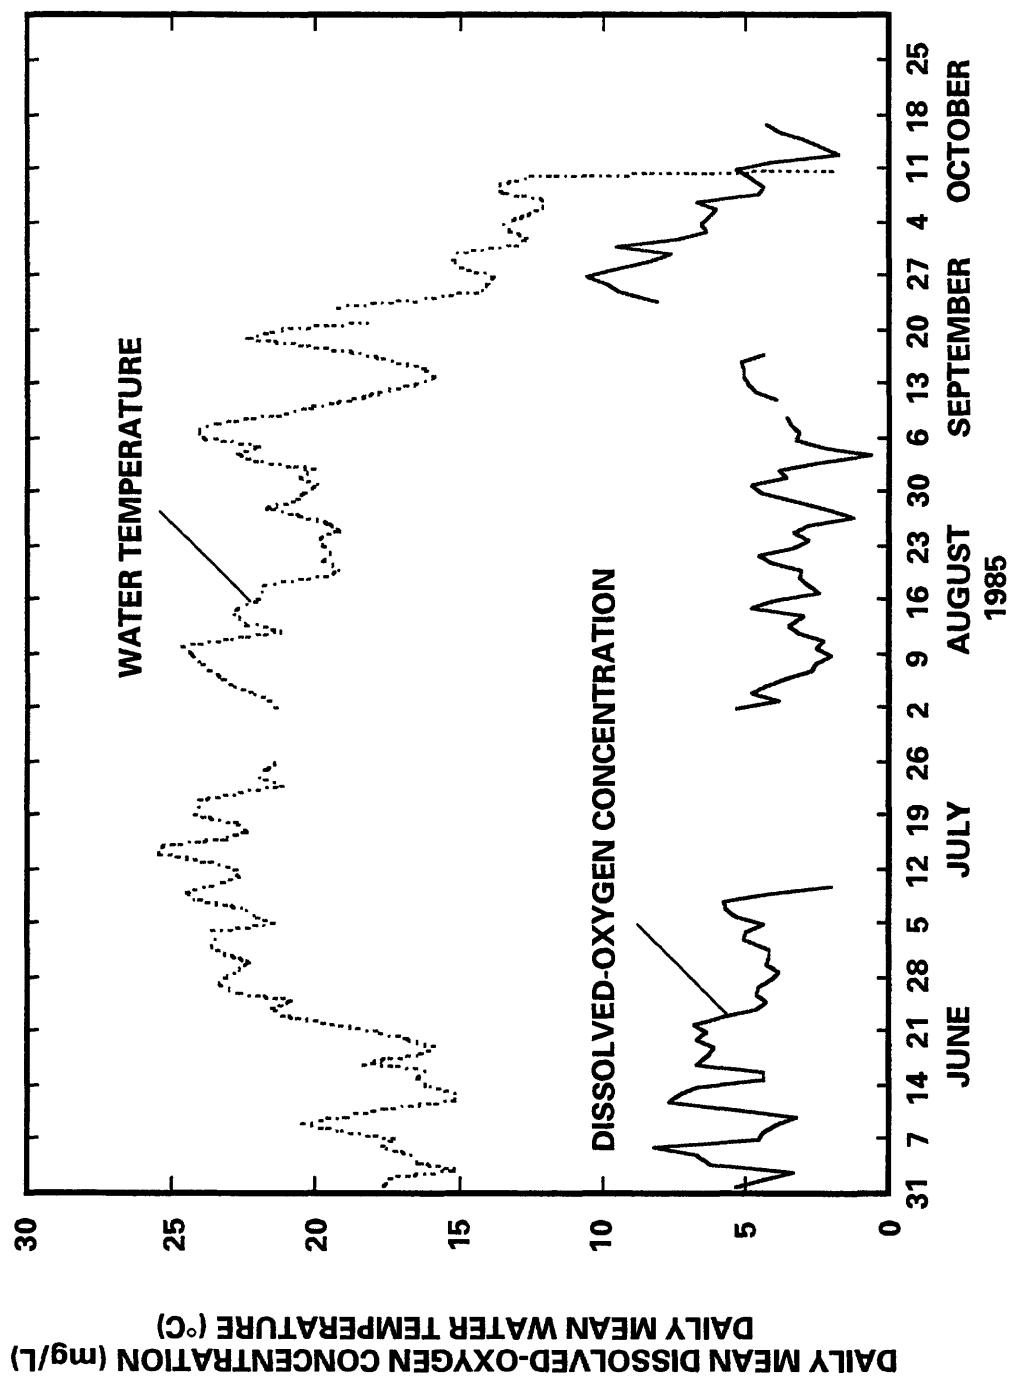

Figure 11. Daily mean dissolved-oxygen concentration and daily mean water temperature for East River at State Highway 32 near De Pere, June-October 1985.

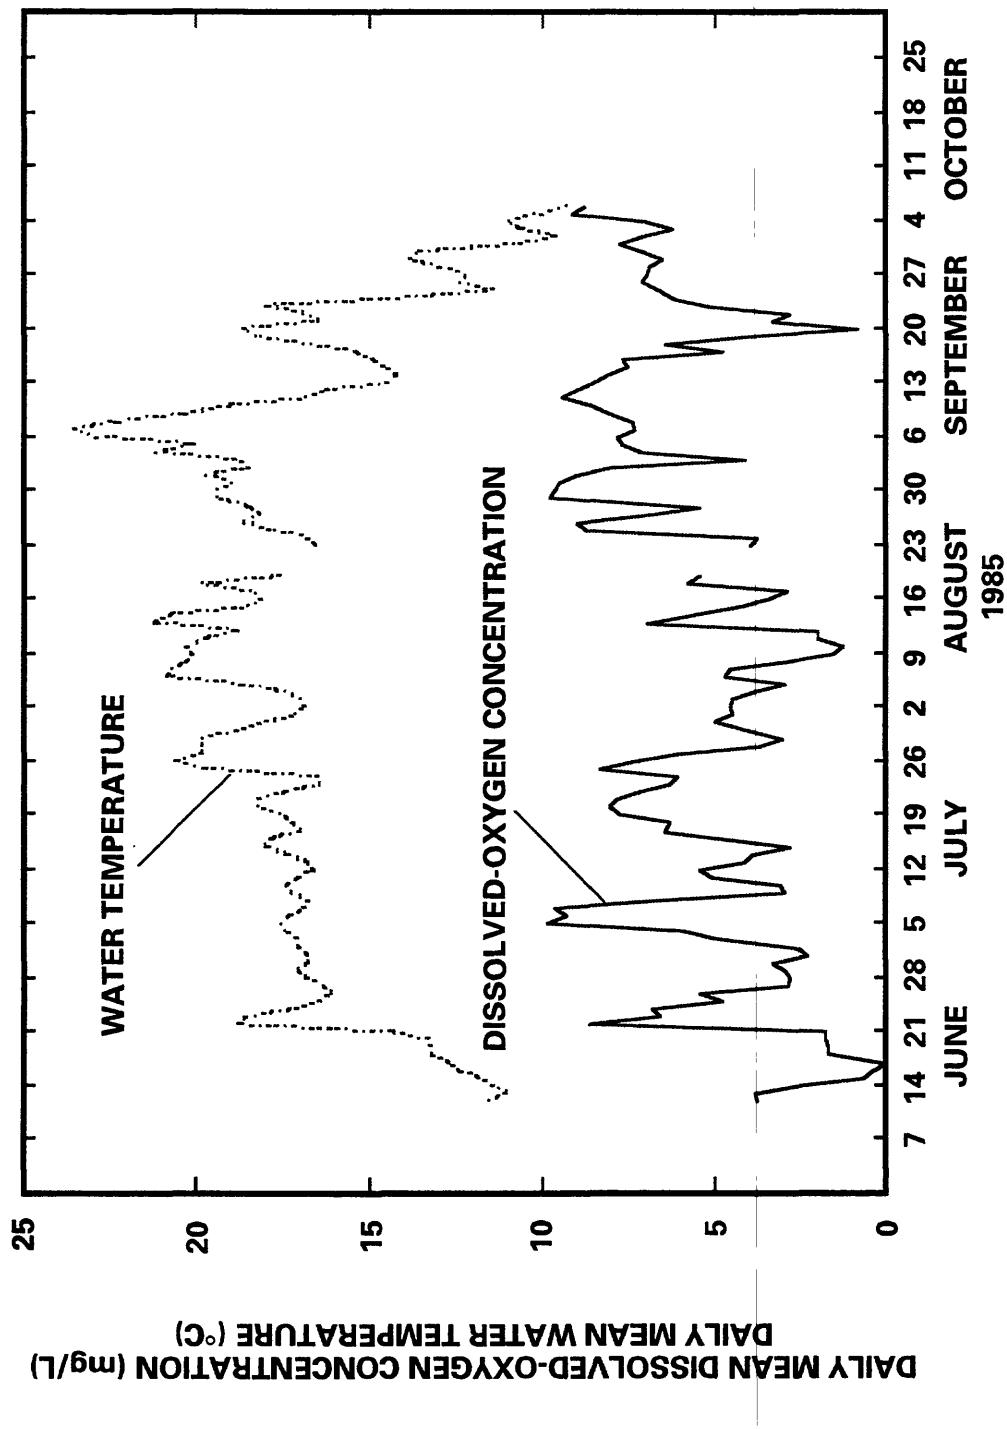

Figure 12. Daily mean dissolved-oxygen concentration and daily mean water temperature for Bower Creek at Sunnyview Road near De Pere, June-October 1985.

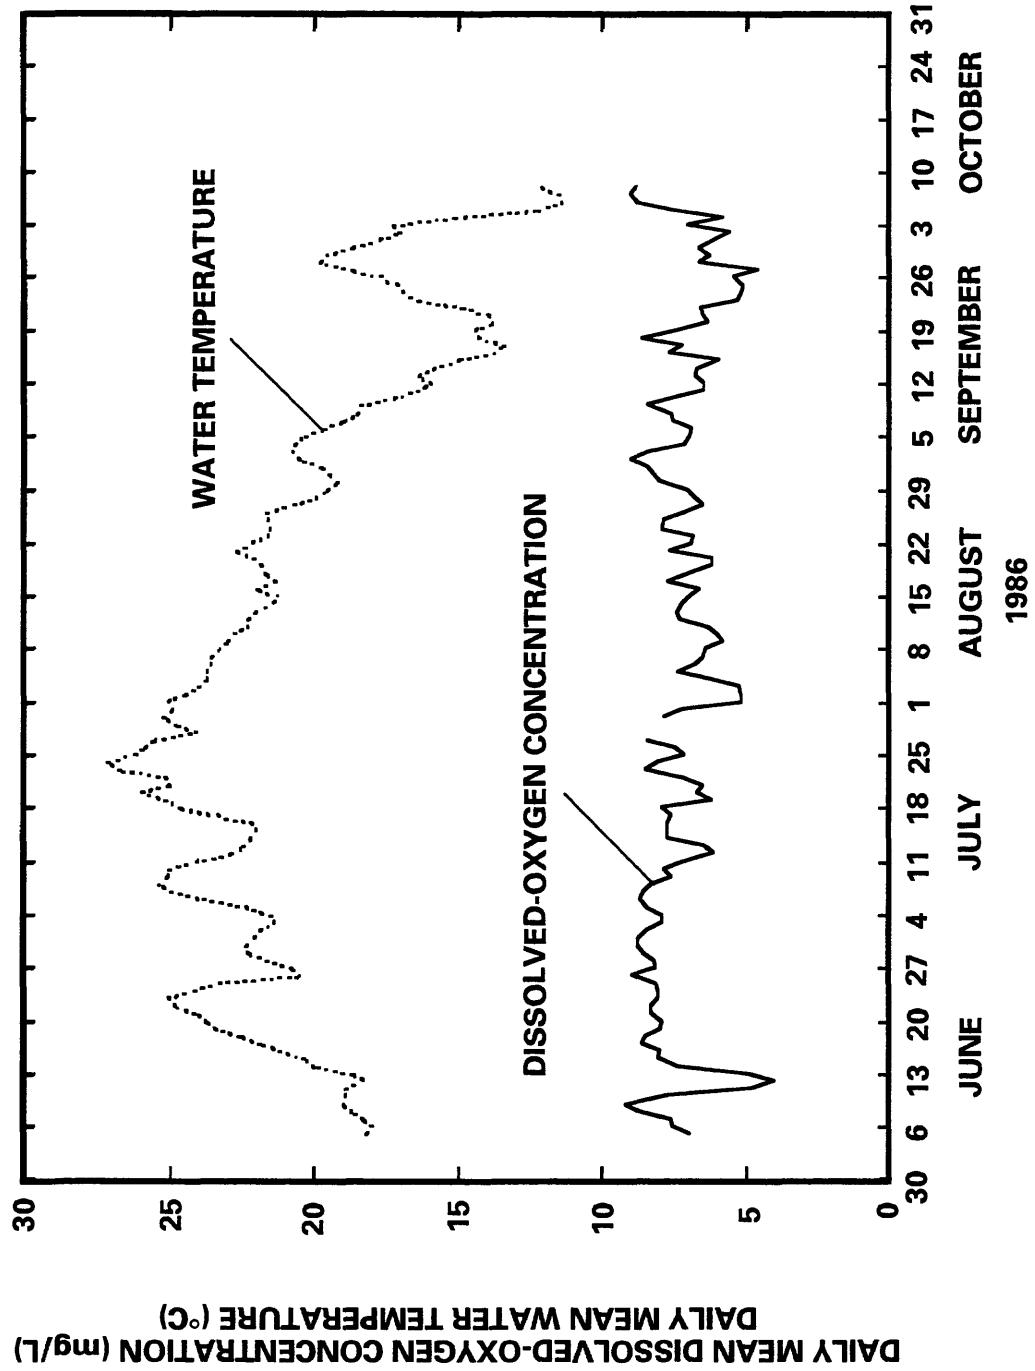

Figure 13. Daily mean dissolved-oxygen concentration and daily mean water temperature for East River at Monroe Street in Green Bay, June–October 1986.

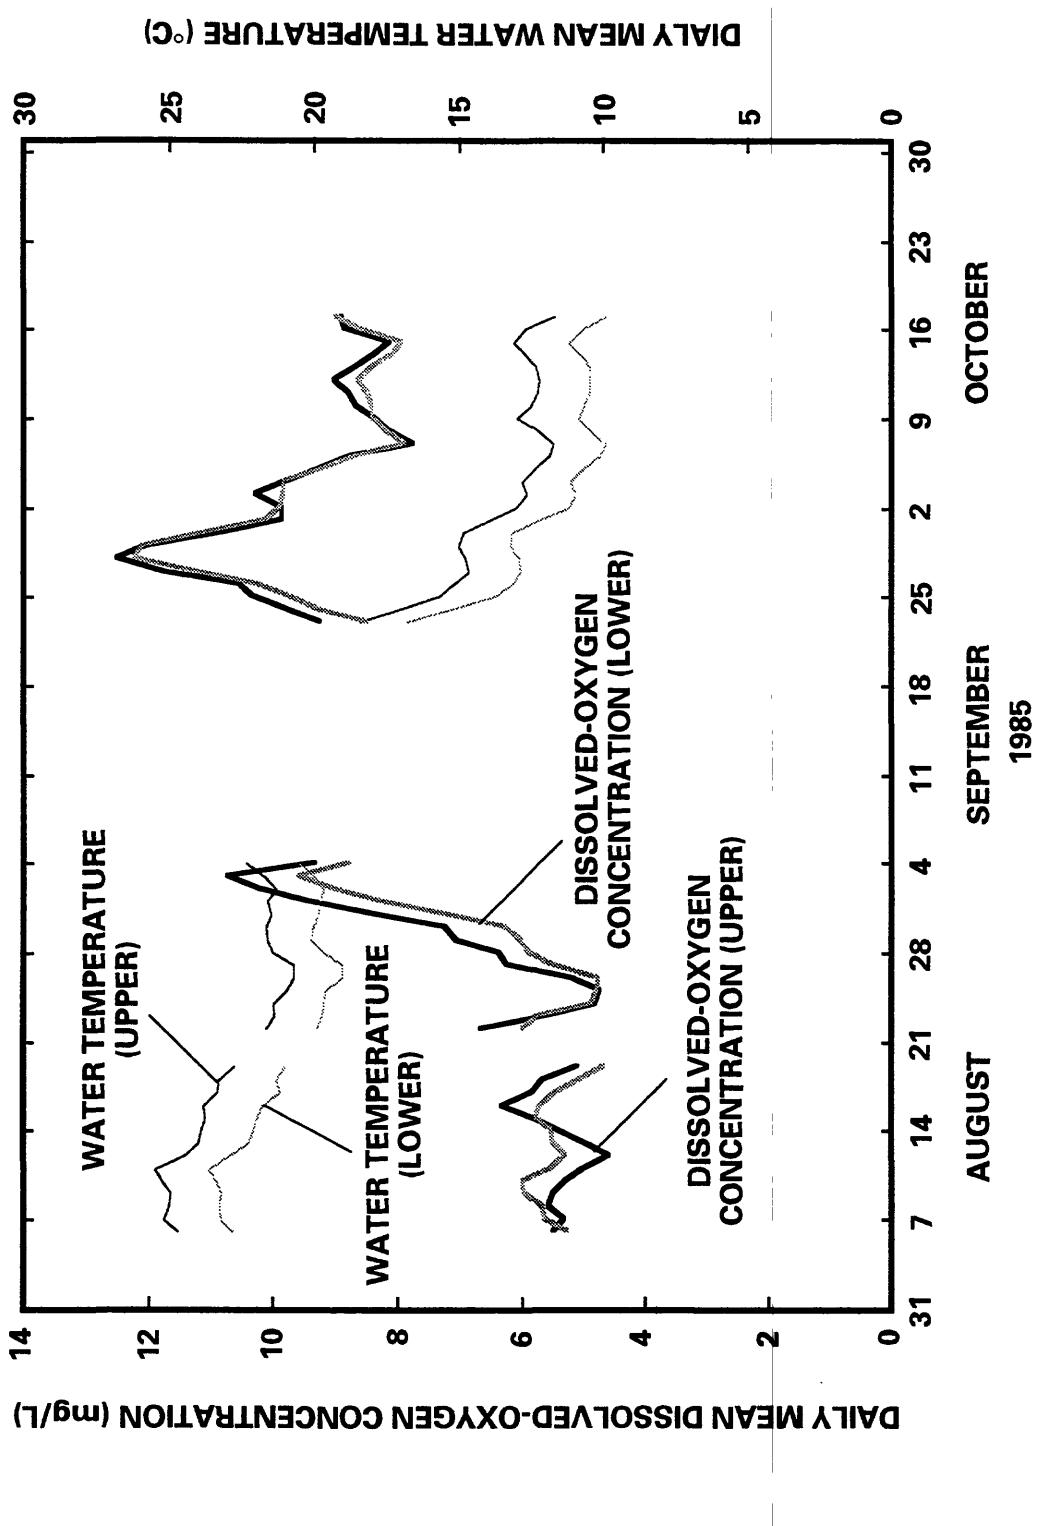

Figure 14. Daily mean dissolved-oxygen concentration and daily mean water temperature for Fox River at Schmidt Oil Dock (upper and lower sites), in Green Bay, August-October 1985.

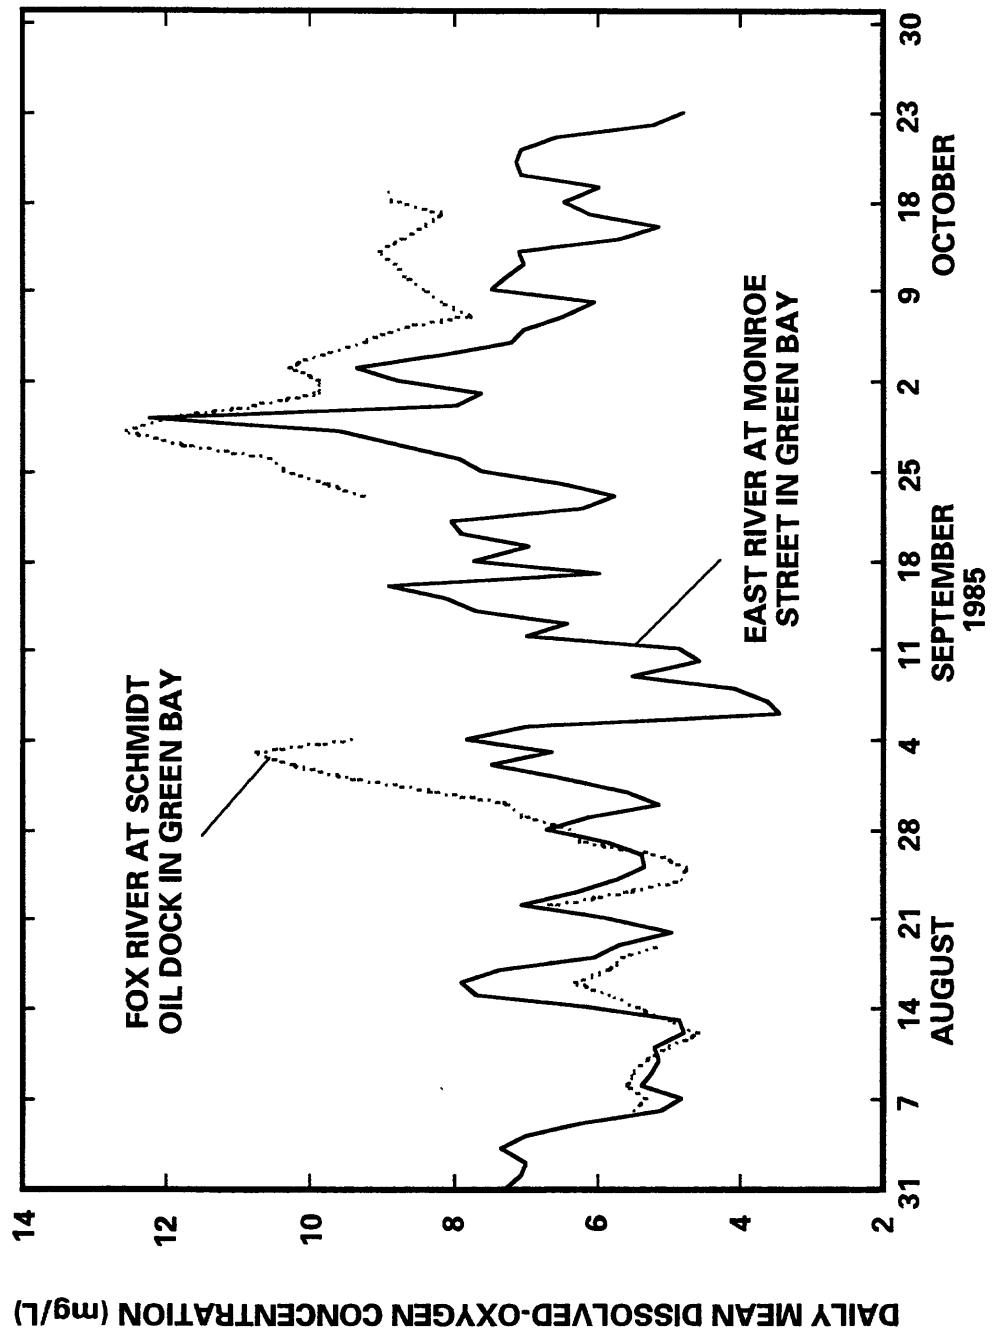

Figure 15. Daily mean dissolved-oxygen concentration for East River at Monroe Street in Green Bay and Fox River at Schmidt Oil Dock, upper site, in Green Bay, August-October 1985.

Samples from all four sites exceeded the acceptable fecal coliform level (Schuettpelz, 1969) for recreational water quality of 200 counts per

100 mL for over 50 percent of the samples. A summary of the results follows:

Site	Number of observations	Percent of observations with fecal coliform counts greater than 200 counts/100 mL	Percent of observations with fecal coliform/fecal streptococcus ratio greater than 4.0
East River at Monroe Street in Green Bay	37	76	27
East River at Allouez Avenue bridge	20	65	20
East River at State Highway 32	19	89	11
Bower Creek at Sunnyview Road	46	91	13

The East River at State Highway 32 and Bower Creek had the highest percentage of samples that exceeded the recreational standard. The East River at Monroe Street in Green Bay and at Allouez Avenue bridge had the highest percentage of samples with fecal coliform/fecal streptococcus ratios greater than 4.0. A ratio greater than 4.0 suggests that the bacteria is human in origin, rather than animal (Schuettpelz, 1967). Because the sites at Green Bay and Allouez are closer to the urbanized portion of Brown County, higher ratios at those sites can be expected. The bacteria concentration data and fecal coliform/fecal streptococcus ratios are listed in Appendix G.

5-day BOD and Chlorophyll a

Ranges and means of 5-day BOD and chlorophyll a concentrations are shown in table 4. Values given for individual sites cannot be readily compared to all other sites because sampling frequency and distribution varied between sites. All sites were sampled biweekly, but the East River at Monroe Street in Green Bay and Bower Creek at Sunnyview Road near De Pere were sampled during many storm events. During the 1985-86 study period, the samples from Bower Creek had the highest mean concentrations for all constituents except chlorophyll a, which was higher at the two most downstream East River sites, at Monroe Street and at Allouez Avenue bridge.

SUMMARY

The U.S. Geological Survey, in cooperation with the Fox Valley Water Quality Planning Commission, collected streamflow and water-quality data from the East River basin in northeast Wisconsin during the period March 1985 through October 1986.

Streamflow for the 1986 water year was greater than twice the 20-year (1967-86) average determined from the gaging station record on the Kewaunee River near Kewaunee. Precipitation was 37 percent greater for 1985 and 12 percent greater for 1986 as determined from the long-term National Oceanic and Atmospheric Administration record at Green Bay (1951-80). Streamflow during the study period ranged from about the 75-percent duration flow at low flow to a peak flow which was greater than the 10-year flood recurrence interval.

The largest suspended-sediment and total-phosphorus loads were observed for the East River at Green Bay during the periods November 1-4, 1985, and March 25-28, 1986. As measured at the gaging station, 27 and 55 percent of the suspended sediment and 21 and 37 percent of the total phosphorus were transported within those periods for 1985 and 1986, respectively. At Bower Creek 31 percent of the suspended-sediment load for 1985 was transported during one storm (June 21-25) and 19 percent of the total-phosphorus load

for 1985 was transported during a second storm (November 1-4). In 1986, one storm (March 16-26) had 63 percent of the suspended sediment and 38 percent of the total phosphorus transported.

Even though the discharge for the East River during 1986 was approximately double that for an average year, the East River still contributes a disproportionately large share of the suspended-sediment and total-phosphorus yields to the Fox River basin when compared to the Fox River data available for the Wrightstown gaging station. Suspended-sediment and total-phosphorus yields from the Bower Creek basin were approximately twice those for the East River at Monroe Street in Green Bay.

Dissolved-oxygen concentrations tended to decrease upstream from the mouth of the East River. The mean daily dissolved-oxygen concentration was often less than 5 mg/L at all three of the East River monitoring locations. Minimum instantaneous dissolved-oxygen concentrations of 1 to 2 mg/L were recorded at all sites.

The acceptable fecal coliform level for recreational water quality (200 counts per 100 mL) was exceeded at all three of the East River sites and Bower Creek for more than half of the samples taken during the study. The downstream sites on the East River at Monroe Street in Green Bay and at Allouez Avenue bridge also had more samples with fecal-coliform/fecal-streptococcus ratios that exceeded 4.0, which indicates that the bacteria is human, rather than animal, in origin.

Bower Creek had the highest mean concentrations for BOD-5, total phosphorus, fecal coliform and fecal streptococcus of all the sites monitored during 1985-86. The East River sites at Monroe Street in Green Bay and at Allouez Avenue bridge had the highest mean chlorophyll a concentrations during the study period.
